1. A load  $P$  will be supported by a structure consisting of rigid bar A, two aluminum alloy bars B ( $E = 10600$  ksi), and a stainless steel bar C ( $E = 28000$  ksi), as shown in Fig. 1. The bars are unstressed when the structure is assembled at room temperature ( $72^\circ\text{F}$ ). Each bar has a cross-sectional area of  $2.00\text{ in}^2$ . The coefficients of thermal expansion are  $12.5(10^{-6})/^\circ\text{F}$  for the aluminum and  $9.6(10^{-6})/^\circ\text{F}$  for the stainless steel. Determine the axial stresses in the bars after a 40-kip load is applied and the temperature is increased to  $250^\circ\text{F}$ . (25%)

2. A group of wooden beams is used as a dam as shown in Fig. 2. To what thickness  $t$  of the beams can the water be raised if the maximum bending stress  $\sigma_{\max}$  is not to exceed 15 MPa? Take  $h = 3.253$  m, and the weight of the water is  $9.81\text{ kN/m}^3$ . (25%)

3. For the statically indeterminate beam as shown in Fig. 3. Please find

- (a) the reactions. (8%)
- (b) the deflection relation. (9%)
- (c) the maximum deflection. (8%)

where  $E$ ,  $I$  are material constants,  $w$  is the uniform distributed load.

4. Fig. 4 shows a small pressurized cylinder, attached at the one end and loaded with a pipe wrench at the other. The internal pressure causes a tangential stress of 200 MPa and an axial stress of 100 MPa that act on an element at point A. The pipe wrench superimposes a bending stress of 50 MPa and a torsional stress of 100 MPa.

- (a) Make a Mohr circle representation of the state of stress at point A. (5%)
- (b) Determine the principal stresses and maximum shear stress at point A. (9%)
- (c) Make a sketch showing the orientation of a principal element (with respect to the original element drawn at A), and show all stresses acting on it. (6%)
- (d) Determine the corresponding principal strains and maximum shear strain at point A if Young's modulus is  $E = 70\text{ GPa}$  and Poisson's ratio is  $\nu = 0.3$ . (5%)
